ABSTRACT

There have been dozens of high-profile mass shootings in recent decades. This paper presents three main findings about the impact of mass shootings on gun policy. First, mass shootings evoke large policy responses. A single mass shooting leads to a 15% increase in the number of firearm bills introduced within a state in the year after a mass shooting. This effect increases with the extent of media coverage. Second, mass shootings account for a small portion of all gun deaths, but have an outsized influence relative to other homicides. Third, when looking at bills that were actually enacted into law, the impact of mass shootings depends on the party in power. The annual number of laws that loosen gun restrictions doubles in the year following a mass shooting in states with Republican-controlled legislatures. We find no significant effect of mass shootings on laws enacted when there is a Democrat-controlled legislature, nor do we find a significant effect of mass shootings on the enactment of laws that tighten gun restrictions.

1. Introduction

Recent decades have witnessed a series of high-profile mass shootings throughout the United States. While most homicides receive little attention from the public, mass shooting incidents are extremely salient. Nonetheless, a common and frequently articulated view is that despite extensive discussion about mass shootings, they have little influence on policymaking.

Should we expect policymakers to propose new legislation in the wake of a mass shooting? Given that the vast majority of gun deaths do not result from mass shootings, it would be difficult to reconcile large responses to mass shootings with basic models of optimal policy aimed exclusively at reducing gun violence. However, mass shootings may have another effect—bringing attention to the issue of gun violence. Mass shootings could potentially lead to policy changes by focusing attention on gun violence, even if they do not provide new information regarding effective policy or change politicians' preferences.

Political scientists have noted that issues tend to rise and fall in importance within a policy agenda, creating periods in which specific policies

shift very rapidly and other periods in which they do not change at all (Baumgartner and Jones, 1993; Kingdon, 1984). In the context of gun violence, events like the Columbine High School shooting in Colorado have led to calls for new restrictions on guns as well as vehement responses from groups that oppose such changes and favor the loosening of gun laws (Goss, 2006; Spitzer, 2012). More generally, mass shootings may create “policy windows” during which legislatures become receptive to change—potentially due to shifts in the attention of the media and constituents. Nonetheless, the extent to which mass shootings affect policy and the nature of the resulting changes are empirical questions.

In this paper, we explore the impact of mass shootings on gun policy, constructing a dataset of all U.S. gun legislation and mass shootings over a period of twenty-five years (1989–2014)—combining data from a variety of media and government sources. We begin by looking at the extent of deaths resulting from mass shootings relative to other gun deaths. Overall, there are more than 30,000 gun related fatalities in the United States per year. Approximately 56% of these are suicides and 40% are homicides. The remaining 4% are accidents or incidents of undetermined intent. Mass shootings accounted for about 0.13% of all gun deaths and 0.34% of gun murders between 1989 and 2014.

Because mass shootings are salient and plausibly random occurrences, we are able to implement a difference-in-differences strategy around the timing of mass shootings to estimate their causal impact on gun regulation. Specifically, we compare gun laws before and after mass shootings, in states where mass shootings occur relative to all other states.

We then present three main findings about the impact of mass shootings on policy. First, mass shootings evoke large policy responses.

A single mass shooting leads to an approximately 15% increase in the number of firearm bills introduced within a state in the year after a mass shooting. This effect is largest after shootings with the most fatalities and is greatest in states with Republican-controlled legislatures.

Second, although mass shootings account for a small portion of all gun deaths, they have an outsized influence relative to other homicides. Our estimates suggest that the per-death impact of mass shootings on bills introduced is much larger than the impact of gun homicides in non-mass shooting incidents.

Third, when looking at enacted laws, the impact of mass shootings depends on the party in power. In states with Republican-controlled legislatures, a mass shooting roughly doubles the number of laws enacted that loosen gun restrictions in the year following the incident. We find no significant effect of mass shootings on laws enacted when there is a Democrat-controlled legislature. We also find no significant effect of mass shootings on the number of enacted laws that tighten gun restrictions.

These findings contribute to the political economy literatures on public attention, accountability, policymaking, and law. Empirical research on policymaking emphasizes that factors beyond social welfare—such as ideology, opportunism, and fiscal considerations—influence policy (Makowsky and Stratmann, 2009; Bardhan and Mookherjee, 2010). As we show, mass shootings cause intense legislative activity despite accounting for less than 1% of firearm deaths, suggesting factors beyond optimal deterrence affect debates concerning gun policy.

Additionally, our results contribute to the literature on issue selection and salience, which examines when and why politicians emphasize or downplay elements of their policy platform (Riker, 1996; Petrocik, 1996; Dragu and Fan, 2016). Our finding that Republican-controlled states loosen restrictions on firearms following mass shootings is consistent with the literature's prediction that politicians in the majority tend to focus policymaking on issues they "own"—i.e. those which they have a reputation for successfully handling in the interests of their constituents. Using this definition, and at least during our sample period, Republicans do appear to have "owned" the gun issue (Goss, 2006).

Finally, our results relate to the literature on media and public attention (Eisensee and Strömberg, 2007; Durante and Zhuravskaya, 2018). We find that mass shootings receive considerable media attention and that this attention is correlated with the number of gun bills introduced following mass shootings, suggesting that increased attention is a plausible mechanism for the higher levels of legislative activity we observe following mass shootings. This sheds light on the role of attention and salience in policymaking, and on the interaction between issue salience and political preferences in shaping the degree and direction of enacted policies.

2. Background and data

As described above, of the roughly 30,000 annual gun deaths in the United States during our sample period, fewer than 100 occur in mass shootings. For the purpose of this paper, we define a "mass shooting" as an incident in which 4 or more people, other than the perpetrator(s), are unlawfully killed with a firearm in a single, continuous incident that is not related to gangs, drugs, or other criminal activity. This definition closely matches the one used by Krouse and Richardson (2015) and the FBI's definition of "mass murder" as 4 or more murders "occurring during the same incident, with no distinctive time period between the murders... typically involv[ing] a single location" (Morton and Hiltz, 2008). We further restrict our analysis to cases where at least three of the fatalities were individuals unrelated to, and not romantically involved with, the shooter(s). We include spree murders—homicides that occur at multiple locations, but with no significant pause between incidents—if they result in four or more deaths.

We assemble a list of mass shootings since 1989 from a variety of government and media sources because there is no single, comprehensive government database of mass murders. We first extract all gun-related mass murders (four or more dead) that are not felony related from the

FBI supplementary homicide reports (SHR). We then verify each incident in the SHR using media accounts; the SHR may contain errors in which separate homicides in a month are reported as a single incident, which is why it is necessary to verify the incidents with media coverage. Participation in the SHR program is voluntary and many law enforcement agencies do not report detailed data to the FBI. We therefore supplement the FBI data with mass shootings gathered from media accounts or compiled by other researchers and journalists interested in the topic. Specifically, we combine the SHR data with data on mass shootings collected by the Mass Shootings in America (MSA) project at Stanford University (Stanford Geospatial Center and Stanford Libraries, 2015) and a list created by USA Today (2013). For each shooting, we determine the event location as well as the number of victim fatalities and injuries. We also classify shootings based on the relationship (if any) between the alleged shooter(s) and victims. Previous work on mass shootings (Duwe, 2007; Krouse and Richardson, 2015) distinguishes between public mass shootings that occur in places frequented by the public, felony-related murders, and familicide. We categorize shootings by whether they are public events or primarily related to domestic conflicts, and we focus on incidents in which at least three people not related or romantically involved with the shooter died. This restriction filters out family-killings in residences as well as family-related murders in public places.¹

Fig. 1 shows the number of incidents and fatalities in mass shootings by year. The data show a slight upward trend in the number of incidents and fatalities over time, but both incidents and fatalities vary substantially from year to year. Fig. 2 shows a map of the locations of mass shootings in the United States between 1989 and 2014.

2.1. Gun legislation

State governments are the primary regulators of firearms. Federal laws establish a minimum level of gun control, which is augmented to varying degrees by state and local policies. The federal government has put some restrictions on firearm commerce, the possession of guns by potentially dangerous individuals, and ownership of certain types of firearms and ammunition. States decide a variety of gun policies, including who can purchase and possess a gun, what types of guns are allowed in different places, how guns should be stored, and what training must be undertaken by gun owners. Local ordinances can also restrict firearm possession and use, but state statutes enacted in the past few decades have limited the importance of local government in this arena by pre-empting local regulations.

We create a comprehensive dataset of gun legislation in all fifty states using the bill tracking reports service from LexisNexis, which includes all bills introduced in state legislatures since at least 1990 with a synopsis and timeline of each bill's progress. This allows us to determine whether bills pass the legislature and become law. We identify firearm bills by searching for the firearm-related terms "firearm", "handgun", "pistol", "revolver", "rifle", "shotgun", "long-gun", and "assault weapon." We identify 20,409 firearm bills and 3199 laws between 1990 and 2014. In other words, there were 20,409 *proposals* made and 3199 laws passed in the twenty-five-year sample period across all fifty states. This includes laws that loosen or tighten gun restrictions, and many that do neither or both. We exclude resolutions, executive orders, and ballot initiatives from the analysis.² Fig. 3 shows the total number of bills introduced and laws enacted by year.

¹ A 2006 shooting at a church in Louisiana is one example. A man killed his wife and in-laws while abducting her and their children from a church. Only the wife's family was present at the church during the shooting.

² Our data source—Lexis Advance—includes resolutions, but it's unclear whether it includes all executive orders or ballot initiatives. Including those we do have along with all resolutions does not meaningfully change the results—the correlation between our measure of legislation and a measure including these other actions is 0.99. In addition, legislators in some states first submit ideas for bills in the form of a "draft request" or similar document. We exclude these from our analyses because they result in double counting some legislation. We instead focus only on actual bills.

Fig. 1. Mass shooting incidents and fatalities by year, 1989–2014. The upper panel shows the number of fatalities in mass shootings in which at least 3 people not related or romantically connected to the shooter were killed. The bottom panel shows the number of these incidents. Washington, D.C. is not included in the sample.

To explore whether gun control is tightened or loosened after mass shootings, we hired eight people to manually code the summary of bills that became law. Coders were given instructions explaining how to code legislation, but were otherwise blind to the topic and design of the study. We presented bill summaries from LexisNexis to coders in

randomly chosen groups of 50. Two people coded each summary, and no coder saw the same summary multiple times. For each summary, coders decided whether the bill was tightening (stricter gun control), loosening (weaker gun control), uncertain (insufficient information), both tightening and loosening, or neither tightening nor loosening

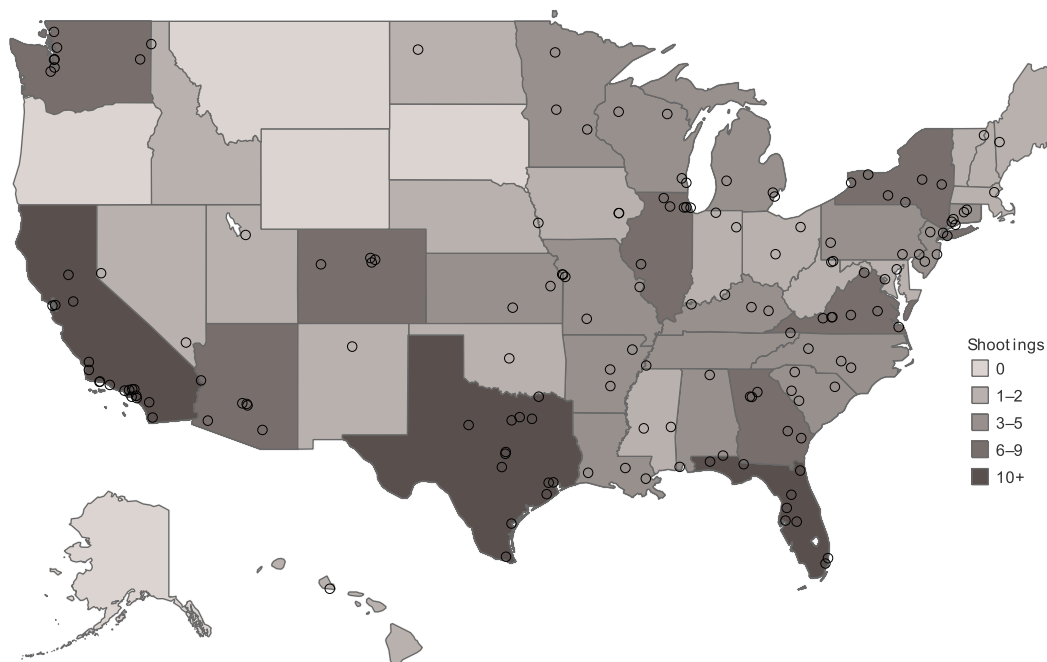

Fig. 2. Locations of public mass shootings in the United States, 1989–2014. States are shaded based on the total number of shootings during the sample period. Points represent the locations of events.

Fig. 3. Total gun bills introduced and laws enacted by year, 1990–2014.

(neutral). There were therefore five possible labels for bills: tighten, loosen, both, neutral, or uncertain. Appendix A shows example bill summaries and their expected labels.

To cross-validate (and incentivize) the bill coding, we coded a small fraction of bills ourselves as a baseline comparison point. For this process, we blinded ourselves from any information about when or where the bill was proposed. We then used our scores to assess the quality of coders. Specifically, each group of 50 bills given to a coder contained five bills that we had also coded (they did not know which bills were and weren't coded by us, and did not have access to any of our assessments of whether a bill loosened or tightened gun restrictions). Coders were paid up to a 50% bonus based on the extent to which their coding matched ours (which we simply told them was a “gold standard” of known codes).

Across all five categories, the two coders for each bill agreed with each other 52% of the time (the agreement rate would be 20% by chance) and agreed with the gold standard 71% of the time. Coders performed worst on the neutral category, and best on the tighten-only and loosen-only categories; when a bill tightens gun control (according to the gold standard), the two coders agree on tightening 67% of the time, and when a bill loosens gun control, they agree on loosening 60% of the time. The fact that coders were not able to agree on a category for 48% of laws reduces the sample available for analysis and is a limitation of our study. In principle, laws might be unclear for coders either because the law is relatively minor and intended to be window dressing, or because it was complicated for the coders to read (leading to coder errors or ambiguity). To explore, we compared 100 random laws that coders disagreed about to 100 they agreed on. We then classified each as a minor (e.g. convening a committee to study an issue) or major (e.g. allowing guns in schools) policy change. We find a similar number of minor laws in both samples, suggesting that coder disagreement likely results from coder inattention rather than laws being especially likely to be minor policy changes. We do not see differences in the rate of disagreement among coders about laws enacted in the wake of a mass shooting, relative to laws enacted at other times. Appendix A includes a breakdown of the coding for all 3199 laws, further discussion of coder agreement, and examples of bills that coders found difficult.

Most importantly for the purposes of our analysis, however, is that when the two coders of a bill agree with each other on tightening, they also agree with our coding 93% of the time; when the two coders agree on loosening, they are consistent with our scores 91% of the time. When analyzing the direction of policy change, we leverage this

high degree of reliability by restricting our analysis to laws that coders agreed were designed to tighten or loosen gun control.³ Because states can pass either, none, or both types of laws in a year, our dependent variable is the count of laws in each direction.

Fig. 4 shows mean bills introduced, laws enacted, and tightening and loosening laws by political control of the state legislature. Republicans enact more laws loosening gun control, and fewer laws tightening gun control, than do Democrats. Republican, Democratic, and split legislatures enact a similar number of total gun laws. The coders who classified the legislation were only given summaries of each bill; they were not provided with the state, year, or any information on political affiliation.

2.2. Control variables

Our main specification controls for state and year fixed effects, as well as an indicator for whether the legislature is in a regular session in the given year, and whether it is the first year of a legislative biennium (since bills are more likely to be enacted then). Specifically, we create two dummy variables. First, we create a dummy for legislatures that held a regular session in a given year because not all legislatures meet annually. Legislatures that are not in regular session would have to rely on special sessions, which can be difficult to call, in order to consider new gun legislation (though some do this). Second, we control for the first year of each legislative biennium (a two-year period of law making), which varies by whether states hold elections in odd or even years. Typically, more bills are introduced during the first year of the biennium, which leads to alternating years of high and low bill introductions (Fig. 3). Building on this main specification, we then add time varying controls as a robustness check. These include economic and demographic factors such as unemployment, divorce rates, and rates of military service. We then layer on controls for the political party in power, since the direction of proposed changes often vary between Democrats (who generally favor more restrictive gun laws) and Republicans (who generally favor less restrictive gun laws). Table 1 contains summary statistics for all variables used in the analyses.

³ This is 37% of all enacted laws in our data. As mentioned, nearly half of laws cannot be categorized because coders disagreed on the classification. Another 13% are not used because coders agreed they were neutral or uncertain.

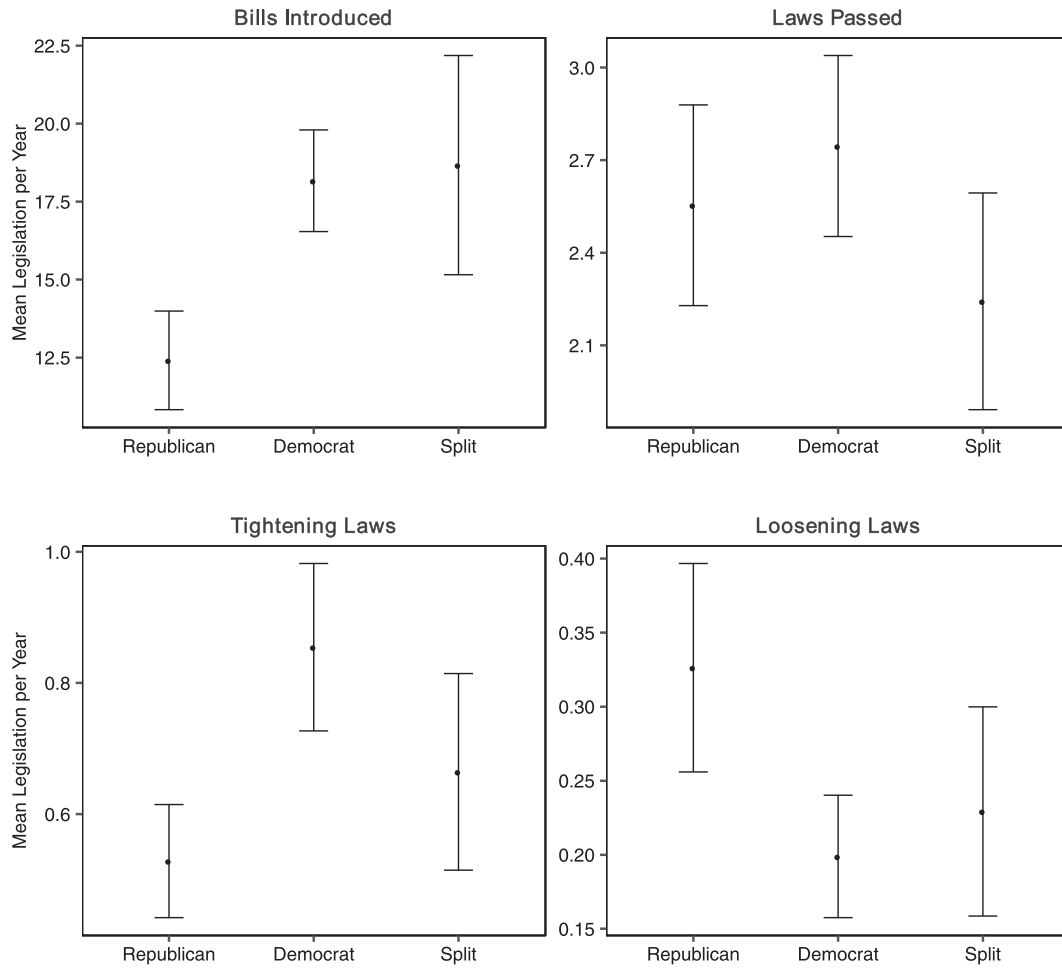

Fig. 4. Comparison of annual legislation introduced by political party. Points represent the mean and lines are 95% confidence intervals. Legislature control means one political party includes both chambers of the legislature. The counts of tightening and loosening laws are based on laws with coder agreement (see Section 2.1 of text).

3. The impact of mass shootings on gun policy

3.1. Identification strategy

We implement a difference-in-differences strategy that compares gun laws before and after mass shootings, in states where mass shootings occur relative to all other states. Our dependent variables are counts of bills or enacted laws at the state-year level. We study the effect of mass shootings using Poisson regressions with conditional mean:

$$E[y_{s,t} | \alpha_s, \lambda_t, Shoot_{s,t-1}, X_{s,t}] = \exp(\alpha_s + \lambda_t + \delta_s t + \beta Shoot_{s,t-1} + \gamma' X_{s,t})$$

where $y_{s,t}$ is a count of bills introduced or laws enacted in state s and year t ; α_s and λ_t are state and year fixed effects; the $\delta_s t$ are state-specific time trends; $Shoot_{s,t-1}$ is either an indicator for states with a mass shooting or the fatality count in mass shootings, and $X_{s,t}$ is a vector of time-varying political, economic, and demographic factors. We estimate the parameters via maximum likelihood by conditioning on the sum of $y_{s,t}$ within states and including year indicators.⁴

⁴ It is possible that the number of bills introduced in a given year within a state would depend on the number introduced in recent years in ways that we do not capture with the state fixed effects or time trends. To allow for this possibility, we also estimated an exponential feedback model in which past legislative activity can affect current activity. Our results suggest past legislation does not substantively affect current legislation; state fixed effects adequately capture time series persistence in legislation and the coefficient estimate for the impact of mass shootings is similar in the exponential feedback model.

Our identification allows us to measure the impact of a mass shooting within that state, controlling for other changes that are happening at the national level. Because this identification strategy does not identify national responses to mass shootings (which would be absorbed by our year effect), our estimates of changes in gun policy may underestimate the total impact of a mass shooting. We can and do account for potential spillovers into neighboring states, but do not see significant spillover effects; these results are presented in Appendix B.

3.2. The effect of mass shootings on gun bill introductions

Table 2 shows that a mass shooting leads to a 15% increase in firearm bills introduced (column 4).⁵ For the average state, this amounts to an additional 2.4 firearm bills introduced in the year following a mass shooting. Mass shootings with more deaths lead to larger effects. On average, each additional death in a mass shooting leads to a 2.3% increase in the number of gun bills introduced (column 8). These results hold for both Republican-controlled and Democrat-controlled legislatures, for alternative victim thresholds used to define mass shootings, models that

⁵ We calculate our effect sizes as percentage changes in the expected value of the dependent variable when there is a mass shooting vs. when there is no mass shooting, treating the mass shooting variable as a dichotomous indicator. These numbers differ slightly from the predicted percentage change from differentiating the conditional expectation function (i.e. 100 times the coefficient estimate).

Table 1
Summary statistics.

	Mean	sd	p5	p10	p50	p90	p95
Gun legislation							
Bills introduced	16.33	22.04	0	1	10	38	53

Divorce %	11.8	1.8	8.9	9.5	11.8	14.1	14.7

Note: Sample includes 1250 state-year observations from 1990 to 2014. *Bills introduced* is the number of bills introduced in the legislature; *Laws enacted* is the number of bills that became law. *Tightening* and *Loosening laws* are numbers of enacted laws that tightened and loosened gun control respectively. *Mass shooting* is an indicator for state-years with a mass shooting in which three or more people not romantically involved with or related to the shooter(s) were killed. *Fatalities* is the total number of deaths in mass shootings in a state-year. *The Gun homicide rate* is expressed as deaths per 100,000 residents. *News coverage* is the hours of nightly news coverage of mass shootings occurring in a state. *Democratic* and *Republican legislature* are indicators for party control of the state legislature. *Republican governor* is an indicator for Republican governors. *Regular session* indicates whether the legislature convened a regular (as opposed to special) session to consider bills; some state legislatures only meet every other year. *First year of biennium* is an indicator for the first year of the two-year legislative biennium (the calendar year immediately following elections). *Income per capita* is measured in thousands of 1987 U.S. dollars. Other demographic variables are percentages.

examine the year of the shooting in addition to the previous year, and models that use the log of fatalities instead of the count.⁶

3.3. Comparing mass shootings and non-mass shootings

Table 3 shows that fatalities resulting from mass shootings lead to much larger increases in gun bill introductions than gun homicides in non-mass shooting incidents. We estimate the models in this table using mass shooting fatalities and ordinary gun homicides per 100,000 people to facilitate comparison between the two types of murder. Our estimates are imprecise, but suggest it would take approximately 125 people dying in individual gun homicide incidents to have as much impact on bills introduced as each person who dies in a mass shooting. There are, however, a number of caveats to this estimate. First, ordinary gun homicides are less random than mass shootings and therefore not exogenous in the model. Second, the victims of mass shootings and ordinary gun homicides have different attributes; the impact of mass shootings is not easily decomposed into the effect of victim count, media salience, and attributes of the victims. Any differences in response between ordinary and mass shootings could be driven in part by attributes of the victims. Our estimates, however, are still suggestive evidence that mass shootings tend

to have a greater impact on legislative activity than changes in the ordinary gun homicide rate.

3.4. The role of political party on laws enacted

As mentioned previously, the two major political parties in the United States differ dramatically in their stances on how restrictive gun policy should be, with the Republican Party favoring fewer gun restrictions.⁷ To look at the impact of political parties on gun policy, we restrict our analysis to enacted laws, all of which were coded for whether they loosened or tightened gun restrictions (see data description for more details).

Tables 4 and 5 show the effect of mass shootings interacted with Democrat and Republican control of state legislatures. The results show that Democrats and Republicans respond differently to mass shootings. Table 4 shows that Republicans introduce 50% more bills and Democrats introduce 11% more bills following mass shootings than in other years, although the coefficient for Democrats is not statistically significant.⁸ The results also indicate that Republican legislatures enact 32% more laws the year after a mass shooting than in other years, a statistically significant increase. Democratic legislatures enact 7% more laws the year after a mass shooting, but this estimate is imprecise and not statistically significant.⁹

When there is a Republican-controlled legislature, mass shootings lead to more firearm laws that loosen gun control (Table 5). Our point estimates indicate that a mass shooting in the previous year increases the number of enacted laws that loosen gun restrictions by about 120% in states with Republican-controlled legislatures. When there is a Democrat-controlled legislature, mass shootings lead to a statistically insignificant reduction in laws that loosen gun control. This result is similar across models using the count of fatalities instead of a shooting indicator, across alternative victim thresholds, with or without year fixed effects, with or without control variables, and when we include only a limited set of controls.¹⁰ We find no significant effects of mass shootings on laws that tighten gun restrictions, but the estimates are imprecise.

The finding that Republicans—who typically favor fewer restrictions on gun owners—are more active in introducing and passing new legislation following mass shootings is consistent with hypotheses in the literature on how issue salience affects policy decisions (Riker, 1996; Petrocik, 1996; Dragu and Fan, 2016). These models of issue selection suggest that Republican-controlled legislatures might respond to increased attention to gun policy by introducing new legislation because Republican voters: (a) tend to be in favor of expanding gun rights and access to guns (Parker et al., 2017), (b) often argue that such actions reduce gun crime (Parker et al., 2017), and (c) are more likely than Democratic voters (during our sample period) to mobilize for political action on this issue (Goss, 2006).¹¹ Research suggests that supporters of gun rights are more likely to advocate for their positions by writing letters or donating money (Schuman and Presser, 1981) and are better-organized than citizens favoring gun control during our sample period;

⁷ See, for example, <https://www.gop.com/platform/> and <https://www.democrats.org/party-platform>.

⁸ The difference between Republicans and Democrats is statistically significant at the 0.05 level.

⁹ The difference between Republicans and Democrats in terms of enacted laws is not statistically significant. Without interacting mass shooting with political party, there is a 9% increase in gun laws enacted (i.e. bills that become law) after a mass shooting relative to other years, but this estimate is imprecise (Appendix C).

¹⁰ Available from authors upon request. The coefficients tend to be larger in magnitude for shootings resulting in more deaths (e.g. a dummy for shootings that causes 6–9 deaths has a larger coefficient than a dummy for shootings causing 4–5 deaths). The effect for tightening laws is statistically significant and positive—for both Democrats and Republicans—only for shootings causing 10+ deaths. This result, however, is identified from only 11 state-year observations due to the rarity of mass shootings that kill 10 or more people.

¹¹ Republicans appear more likely than Democrats to enact new gun legislation in the absence of a mass shooting (see Table 4, $p = 0.08$).

⁶ Results by political affiliation are presented in Table 4 and discussed in section 3.4 below. Results using alternative victim thresholds for the definition of mass shooting (e.g. 5+, 7+, 10+ deaths) and alternative models are available from the authors upon request.

Table 2

The effect of mass shootings on gun bill introductions.

Dependent variable: number of firearm-related bills introduced in state legislature.

membership in pro-gun-control organizations, for example, is less than 10% of the National Rifle Association's membership (Goss, 2006).¹²

Anecdotally, there are several examples of Republican lawmakers proposing looser gun laws in response to mass shootings. In the year after the mass shooting at Marjory Stoneman Douglas High School, Florida passed legislation allowing teachers and volunteers to carry guns in schools. Republican Rep. Chuck Brannan explained the rationale: "It allows the good guys to stop the bad. The bad guys will never know when

See note to Table 1 for all variable definitions.

laws suggest that there are relevant changes to gun policy following mass shootings. However, it is possible that mass shootings also lead to an uptick in minor proposals as well; legislators may want to signal that they are making changes even if the new laws have only unsubstantial effects on policy in practice. To further examine this possibility, we look at the impact of mass shootings on laws our coders agreed were, neutral since these tend to be more minor proposals (e.g. changing the official who is responsible for storing certain records). As seen in Appendix D, we do not see statistically significant changes in the number of neutral law changes, although the point estimate is positive.

3.5. Media coverage and mass shootings

To explore the potential role of media in increasing the salience of mass shootings, we assemble a dataset of television news coverage related to guns. We measure the seconds of gun-related news coverage on the national, evening news programs of the three major television networks—NBC, ABC and CBS—using data from the Vanderbilt Television News Archive (VTNA).¹⁵ This source has been used in prior research to measure media attention to natural disasters (Eisensee and Strömberg, 2007) and the Israeli-Palestinian conflict (Durante and Zhuravskaya, 2018). We exclude cable news networks because data on their news coverage is not available for our sample period. To calculate total gun-related news coverage, we take all news segments that mention gun-related words in either the segment title or summary provided by VTNA and exclude segments that include the names of foreign countries.¹⁶ We then sum the duration of these news stories by day to create a measure of total gun-related news coverage.

To capture variation in news coverage across shootings, we aggregate news coverage in the ten days following each mass shooting (including the day of the shooting). The five most covered mass shootings between 1989 and 2014 are the shootings at Sandy Hook Elementary School, a Gabrielle Giffords constituent meeting, Virginia Tech, an Aurora movie theater, and Columbine High School.

Mass shootings increase gun-related media coverage, and shootings that kill more people result in more coverage. Fig. 5 shows total seconds of evening news coverage devoted to gun-related stories around the time of mass shootings. Mass shootings resulting in 10 or more fatalities receive substantially more coverage than shootings resulting 6–9 fatalities, which in turn receive more coverage than shootings with 4–5 fatalities. Appendix E provides further support for this relationship in the form of regression results.

To examine whether the amount of gun-related news coverage following a mass shooting affects policy, we add the measure of media coverage to our model by totaling the amount of gun-related news coverage following each shooting within a state during the previous year. The results in Table 6 show that the coefficient on news coverage is positive and statistically significant, indicating that more media attention is associated with a greater policy response. One hour of gun-related news coverage following a mass shooting is associated with a 13% increase in the number of gun-related bills introduced in state legislatures (column 4). This suggests that increased salience of gun policy after mass shootings is a plausible mechanism for the relationship between shootings and gun legislation. Media coverage, however, is strongly related to the number of fatalities (see Fig. 5), making it difficult to distinguish the impact of media coverage from other attributes of the shooting event.

Unlike other studies of the media's effect on public policy (Eisensee and Strömberg, 2007; Durante and Zhuravskaya, 2018), our ability to detect policy responses to gun-related news coverage is limited by the small number of events and by the delay between when a mass shooting occurs and when legislatures can act, which is usually not until the next legislative session. The natural disasters studied by Eisensee and Strömberg (2007) and military attacks studied by Durante and Zhuravskaya (2018) number in the thousands, whereas we observe 169 mass shootings. Furthermore, these authors focus on executive actions—whether to provide disaster relief (Eisensee and Strömberg, 2007) or launch a military attack (Durante and Zhuravskaya, 2018)—that can be taken within hours or days of an event and its accompanying news stories. Legislative action on the other hand must wait until a legislature is in session and rules allow for the introduction of new bills. Our results overall, however, show that attention shifts to gun violence following mass shootings, and shootings that kill more people receive more media attention. These shifts in

¹⁵ The Vanderbilt Television News Archive is accessible online at <https://tvnews.vanderbilt.edu>.

¹⁶ This filter removes news stories about foreign wars.

News coverage is measured in seconds.

attention are a plausible mechanism behind increased legislative activity related to guns in the year following mass shootings.

3.6. Robustness checks

In this section, we present four sets of robustness checks. First, we collapse our data into two-year intervals (e.g. by legislative biennium) to ensure the saw-edge pattern in bill introductions (see Fig. 3) does not drive our results. Second, we provide support for the exogeneity of mass shootings. Third, we perform a falsification exercise in which we use randomly generated placebo shootings instead of actual shootings; we show there are no effects using the placebo shootings,

providing support for our identification strategy. Fourth, we individually drop each state from the sample and re-estimate the models to ensure our effect is not driven by a single state or shooting event.

3.6.1. Analysis by legislative biennium

Fig. 3 shows that bill introductions vary substantially between odd- and even-numbered years. We believe this pattern is driven by most states starting their two-year legislative biennium in odd-numbered years, following elections in November of even-numbered years. Many states allow legislators to “carryover” bills that do not pass in the first year of the biennium for consideration in the second year. This means the agenda in the second year of each biennium includes both newly

Table 6

Stars following coefficients represent *p*-values less than 0.10 (*), 0.05 (**), and 0.01 (***). *News Coverage* does not appear by itself in the model because we only have data from the national nightly news; the coefficient is therefore absorbed by the year fixed effects. See note to Table 1 for variable definitions.

^a Sample collapsed to two-year intervals and year effects replaced with two-year interval fixed effects.

introduced bills and bills introduced the previous year that have been carried over.¹⁷ Our models control for this pattern by including both year fixed effects and an indicator for the first year of each biennium. To ensure this pattern does not drive our results, however, we estimate models that collapse the data to two-year intervals and regress the total number of bills introduced on the mean of mass shootings (e.g. a variable equal to one if both years of the biennium follow a mass shooting and equal to 0.5 if only one year of the biennium follows a mass shooting). The results are shown in columns 3 and 7 in Table 2, and column 3 in Tables 3 and 6. The coefficient estimates are less precise, but remain statistically significant and suggest similar effect sizes. The estimate in column 3 of Table 2, for example, suggests mass shootings lead to the introduction of 3.5 more bills for an average state.

3.6.2. Determinants of mass shootings

Our ability to identify the causal impact of mass shootings on policy rests on the assumption that they are plausibly exogenous to other factors that would drive gun legislation in a given year. Given the erratic nature of mass shootings, this is a plausible assumption. Nonetheless, one might be concerned that both mass shootings and gun policy are being driven by a third variable. To provide support for our assumption and interpretation, we regress an indicator for whether a mass shooting occurs on economic, demographic, and policy variables.

Consistent with the assumption that mass shootings are exogenous with respect to potential confounds, the results in Appendix F show that, out of 32 variables we consider, only unemployment is significantly associated with a higher probability of mass shootings. Because higher unemployment is also associated with a reduction in gun bill introductions (Table 2), the potential bias of this would work in the opposite direction of our finding—making it unlikely that this is driving our results. To further support our interpretation, we control for unemployment in all models. Importantly, bills introduced, laws enacted, and major gun policies do not predict future mass shootings (Appendix F).

¹⁷ Our analyses count each bill once, including it only in the year it was introduced. We count enacted laws in the year of enactment.

3.6.3. Placebo tests

We perform a falsification exercise based on the insights of Bertrand et al. (2004) and Donald and Lang (2007). Specifically, we randomly assign placebo mass shootings to state-years in which no actual shooting occurred with probability equal to each state's frequency of shootings, and randomly draw a fatality count from the empirical distribution of fatalities. Appendix G shows percentiles of the test statistic based on 1000 repetitions of this procedure and our actual test statistics from Tables 2 and 5. The results suggest our tests do not over-reject the null hypothesis that mass shootings have no effect on gun policy.

3.6.4. Excluding individual states

To ensure our results are not driven by a single state or shooting, we separately remove each state from the sample and re-estimate the models. Appendix H presents graphs of the resulting 50 coefficients for the effect of mass shootings on bills and laws, and coefficients for the Republican and Democrat interaction terms in our analysis of laws that tightened or loosened gun policy. The results show that dropping individual states has little effect on our estimates.

4. Discussion

Mass shootings account for a small fraction of gun deaths in the United States, but have a significant impact on gun policy. More gun laws are proposed in the year following a mass shooting. Furthermore, mass shootings seem to have much larger effects on policy, per fatality, than do ordinary gun homicides. These results are broadly consistent with qualitative research that has hypothesized the possibility of mass shootings precipitating change. For example, Godwin and Schroedel (1998) argue that the Stockton schoolyard massacre in 1989 led to the enactment of California's assault weapons ban. We find large sample empirical evidence that sporadic events such as mass shootings can lead to major policy changes.

We also find that media coverage related to guns increases following mass shootings and that Democrat-controlled and Republican-controlled legislatures differ significantly when it comes to enacting gun laws. Republicans are *more* likely to loosen gun laws in the year after a mass shooting than in other years. The effect for Democrats, which tends toward a reduction in the loosening of gun restrictions after a mass shooting, is statistically insignificant. This result aligns with the prediction from the political economy literature on issue selection, that political parties emphasize issues that they have a reputation for successfully handling in the eyes of their constituents (Riker, 1996; Petrocik, 1996; Dragu and Fan, 2016).

Our findings raise a number of additional questions, and suggest several directions for future research. First, future research might directly explore the preferences of politicians. Republican legislatures could loosen gun restrictions because Republican politicians themselves prefer looser restrictions (as would be the case in a citizen-candidate model) or due to pressure from constituents or interest groups. Consistent with this latter possibility, and our findings, survey evidence suggests that those opposed to increased gun control have historically been more likely than those in favor of additional restrictions to take actions like writing a letter or donating money to support their side (Schuman and Presser, 1981). If constituent preferences are driving results, we might expect increased loosening of gun policies in areas with higher rates of gun ownership. To provide exploratory evidence, Appendix I shows the results from adding a proxy for gun ownership to the models. Following Cook and Ludwig (2006), we calculate the percentage of suicides that are firearm related as a proxy for gun ownership and interact this variable with the mass shooting indicator. The coefficient on this variable is not significant either in isolation or when added to the specification with all political interactions. This suggests that changes in support for guns among a state's residents (as proxied by gun ownership) is not the main driver of the policy changes.

Second, our estimates focus on the impact on policy within the state in which each shooting took place. Some mass shootings get national

media attention and potentially affect policy nationwide, a result that would not be identified by our fixed effects model. One direction for future research is to develop strategies to identify national responses. With respect to our findings, this suggests that the total impact of mass shootings on gun policy may be even larger than our estimates.

Third, there is a large literature on the impact of gun policies on crime (Duggan, 2001; Ludwig and Cook, 2000, 2003; Abrams, 2012; Luca et al., 2017). While some gun policies have been extensively researched, many have been difficult to study, which complicates analysis of which policies would be most effective. The relationship we find between mass shootings and gun policy raises the possibility of using mass shootings as an instrumental variable to further study the impact of gun laws on gun deaths. Unfortunately, in our sample, mass shootings are not a sufficiently

strong instrument to estimate the effects of gun policy on gun deaths, due to their relative infrequency. (Appendix J presents results of this analysis.) This leaves open the possibility of using salient and plausibly random events to instrument for policy changes in future research.

Overall, our results show that even random and infrequent events that account for a relatively small portion of total societal harm (as measured by fatalities in the current study) might nonetheless be crucial levers for policy consideration and change. This does not imply that politicians and policy makers are over-reacting; it may be that on issues where there is usually political deadlock, salient events create opportunities for change that has been sought all along. Whether these changes reflect appropriate responses to the problem remains an open question.

Appendix A. Coding gun laws

This appendix provides examples of coding bills and further investigates coder agreement with our gold standard when deciding whether bills tighten or loosen gun control. As explained in the text, a law can be one of the following five types:

- Tightening (stricter gun control)
- Loosening (weaker gun control)
- Uncertain (insufficient information)
- Both tightening and loosening
- Neutral (neither tightening nor loosening)

Table A1 presents examples of each type and illustrates how coders assigned laws to each category. Table A2 shows the categorization of the gun laws in our sample based on the above coding scheme. Coders agree on the type of law about 52% of the time; about half of these laws tighten restrictions on guns and about 20% loosen restrictions on guns. The remainder are uncertain, neutral, or both tightened and loosened gun policy.

Table A3 shows the frequency of coder responses for bills we classified as tightening or loosening in the gold standard. The most common response is both coders agreeing with the gold standard. When coders do not agree with the gold standard, it is common for at least one coder to supply the right answer and the other coder to be either uncertain or think the bill both tightens and loosens gun control.

The following is an example of a law that tighten gun control, which coders got wrong:

"Increases the penalties for carrying a concealed deadly weapon, when the weapon is a firearm, by reclassifying what is currently a class G felony as a class D violent felony; deletes a penalty provision that is unnecessary and duplicative, since any person previously convicted of a

violation of section 1442 is also a person prohibited under section 1448 of Title 11."

Coders may have seen "deletes a penalty provision" and assumed the law also loosened gun control because they did not read that the provision was "unnecessary and duplicative." The following is an example of a law loosening gun control, which coders got wrong:

"Bars a county or municipality from filing a lawsuit against the manufacturer of firearms or ammunition under certain circumstances; reserves an exclusive right for the State to maintain such an action;

repeals conflicting laws."

Some coders made the mistake of thinking this bill both loosened and tightened gun control, perhaps because "bars" sounds like it relates to tightening and "repeals" sounds like it relates to loosening. Both of these are fairly long synopses; however, the share of coder pairs that supply the right answer is not correlated with the length of the synopsis.

Table A1

Example of coding gun laws.

Id	Summary	Tighten	Loosen	Uncertain
1	Creates a new felony for firing a gun within 1000 ft of an educational facility.	1	0	0
2	Reduces the age limit for purchase of a handgun from 21 to 18.	0	1	0
3	Allows parole officers to carry a loaded firearm while commuting to and from work.	0	0	0
4	Relates to the use of firearms in state parks and campgrounds.	0	0	1
5	Requires a license to operate a gun show. Eliminates the waiting period for firearm sales if the purchaser has a valid permit to carry a concealed weapon.	1	1	0

Note: Table shows examples of coding gun laws based on bill summaries. Coders were given a full manual to explain the meaning of "tighten", "loosen", "neutral", and "uncertain" along with the following examples. This table mimics the appearance of the Excel workbooks used by the coders. The first bill creates a new crime related to firearms. It tightens restrictions on firearms. The second bill makes it easier for people to acquire guns; it loosens restrictions on firearms. The third bill is exclusively about parole officers; it is neutral because it does not affect the general public. The fourth bill is uncertain because the summary is a generic description that does not specify whether the law tightens or loosens restrictions on firearms. The fifth bill both tightens and loosens; it regulates gun shows, but also eliminates a restriction on firearm purchasers.

Table A2

Results of coding gun laws.

Category	Total laws	Percent of total
Coders agree		
Tightening	872	27.3
Loosening	312	9.8
Uncertain	245	7.7

Table A2 (continued)

Category	Total laws	Percent of total
Both (tighten and loosen)	79	2.5
Neutral	173	5.4
Coders disagree	1518	47.5
Total	3199	100.0

Table A3

Coder agreement with tightening/loosening gold standard.

	Neutral	Tighten	Loosen	Both	Uncertain
Tighten					
Neutral	6	39	2	2	5
Tighten		460	11	53	61
Loosen			0	2	0
Both				13	2
Uncertain					30
Loosen					
Neutral	0	3	15	2	5
Tighten		12	45	7	15
Loosen			337	72	29
Both				10	2
Uncertain					8

Note: Gold Standard—either tightening or loosening—in bold. Cell values represent the frequency of two coder responses across all unique pairs of coders who saw a given law.

Appendix B. Effect of shootings in neighboring states

Table B1

Mass shootings in neighboring states, bills and laws.

Dependent variable: number of firearm-related bills introduced or laws enacted in state.								
	Bills introduced					Laws enacted		
	(1)	(2)	(3)	(4)	(5)	(6)	(7)	(8)
Mass shooting	0.142** (0.071)	0.146* (0.079)			0.087 (0.073)	0.077 (0.086)		
Neighbor shooting	−0.049 (0.051)				0.050 (0.056)			
Cen. division shooting		−0.005 (0.041)				0.021 (0.054)		
Fatalities			0.023 (0.007)	0.018** (0.009)			0.013 (0.008)	0.008 (0.009)
Neighbor fatalities			−0.001 (0.004)				0.002 (0.004)	
Cen. division fatalities				0.007 (0.005)				0.006 (0.005)
Institutional controls	Yes	Yes	Yes	Yes	Yes	Yes	Yes	Yes
Political controls	Yes	Yes	Yes	Yes	Yes	Yes	Yes	Yes
Demographic controls	Yes	Yes	Yes	Yes	Yes	Yes	Yes	Yes
State fixed effects	Yes	Yes	Yes	Yes	Yes	Yes	Yes	Yes
Year fixed effects	Yes	Yes	Yes	Yes	Yes	Yes	Yes	Yes
State-specific trends	Yes	Yes	Yes	Yes	Yes	Yes	Yes	Yes
Observations	1250	1250	1250	1250	1250	1250	1250	1250

Note: Robust standard errors clustered by state in parentheses. Stars following coefficients represent p -values less than 0.10 (*), 0.05 (**) and 0.01 (***). *Neighbor* variables refer to states with a shared border; *Cen. Division* refers to states within the same Census division. See note to Table 1 for other variable definitions.

Table B2

Mass shootings in neighboring states and directions of policy change.

Dependent variable: number of firearm-related laws enacted.				
	Tightening laws			Loosening laws
	(1)	(2)	(3)	(4)
Dem. leg. × shooting	0.037 (0.136)	−0.005 (0.134)	−0.287 (0.364)	−0.181 (0.399)
Rep. leg. × shooting	0.007 (0.223)	−0.080 (0.256)	0.794*** (0.263)	0.894*** (0.287)
Split leg. × shooting	−0.275 (0.247)	−0.092 (0.229)	0.136 (0.329)	0.080 (0.379)
Dem. leg. × neighbor shooting	0.208 (0.139)		−0.061 (0.242)	
Rep. leg. × neighbor shooting	−0.266**		0.356	

Table B2 (continued)

Dependent variable: number of firearm-related laws enacted.				
	Tightening laws			Loosening laws
	(1)	(2)	(3)	(4)
Split leg. × neighbor shooting	(0.120) −0.163 (0.207)		(0.244) −0.118 (0.227)	
Dem. leg. × cen. division shooting		0.157 (0.158)		−0.186 (0.238)
Rep. leg. × cen. division shooting		0.015 (0.108)		−0.118 (0.174)
Split leg. × cen. division shooting		−0.254 (0.169)		0.101 (0.254)
Political controls	Yes	Yes	Yes	Yes
Institutional controls	Yes	Yes	Yes	Yes
Demographic controls	Yes	Yes	Yes	Yes
State fixed effects	Yes	Yes	Yes	Yes
Year fixed effects	Yes	Yes	Yes	Yes
Observations	1250	1250	1175	1175

Note: Robust standard errors clustered by state in parentheses. Stars following coefficients represent p -values less than 0.10 (*), 0.05 (**) and 0.01 (***). Models show the effect of mass shootings in Republican, Democratic, and split legislatures; the omitted group in these models is states without a mass shooting. *Neighbor* variables refer to states with a shared border; *Cen. Division* refers to states within the same Census division. See note to Table 1 for other variable definitions.

Appendix C. Laws enacted

Table C1

Laws enacted and mass shootings.

Dependent variable: number of firearm-related laws enacted in state.								
	(1)	(2)	(3)	(4)	(5)	(6)	(7)	(8)

Fatalities					0.011 (0.009)	0.014 (0.009)	0.005 (0.014)	0.013 (0.008)
Regular session	3.399*** (0.766)	3.392*** (0.777)	0.388 (0.716)	3.444*** (0.763)	3.401*** (0.772)	3.393*** (0.784)	0.373 (0.715)	3.443*** (0.769)
First year of biennium	0.037 (0.051)	0.028 (0.051)	0.203 (0.290)	0.022 (0.050)	0.028 (0.051)	0.017 (0.051)	0.178 (0.298)	0.012 (0.051)
Democratic legislature		−0.026 (0.079)	−0.107 (0.093)	0.012 (0.097)		−0.022 (0.082)	−0.103 (0.088)	0.011 (0.098)
Republican legislature		0.260*** (0.090)	0.168 (0.103)	0.218*** (0.083)		0.266*** (0.091)	0.167* (0.100)	0.223*** (0.085)
Republican governor		0.010 (0.048)	−0.039 (0.050)	−0.055 (0.051)		0.012 (0.048)	−0.040 (0.053)	−0.053 (0.050)
Demographic controls	No	No	No	Yes	No	No	No	Yes
State fixed effects	Yes	Yes	Yes	Yes	Yes	Yes	Yes	Yes
Year fixed effects	Yes	Yes	Yes ^a	Yes	Yes	Yes	Yes ^a	Yes
State-specific trends	No	No	No	Yes	No	No	No	Yes
Observations	1250	1250	650	1250	1250	1250	650	1250

Note: Robust standard errors clustered by state in parentheses. Stars following coefficients represent p -values less than 0.10 (*), 0.05 (**) and 0.01 (***). Variables are identical to those in Table 2, except for the dependent variable, which is the number of firearm-related laws enacted instead of the number of bills introduced. See note to Table 1 for variable definitions.

^a Sample collapsed to two-year intervals and year effects replaced with two-year interval fixed effects.

Appendix D. Mass shootings and neutral laws

Table D1

Neutral laws enacted.

Dependent variable: number of neutral firearm-related laws enacted.	
	(1)
Mass shooting	0.114 (0.195)
Dem. leg. × shooting	
Rep. leg. × shooting	
Split leg. × shooting	
Political controls	Yes
Institutional controls	Yes
Demographic controls	Yes
State fixed effects	Yes

(continued on next page)

Table D1 (continued)

Dependent variable: number of neutral firearm-related laws enacted.		
	(1)	(2)
Year fixed effects	Yes	Yes
Observations	1050	1050

Note: Sample size differs from other tables due to states with all zero observations (i.e. no years with neutral laws enacted).

Appendix E. Media coverage and mass shootings

This appendix presents regression results showing that mass shootings are associated with large increases in gun-related news coverage and that increased news coverage is associated with greater legislative activity in the form of firearm-related bills introduced in state legislatures.

Table E1 shows results from regressing the log of each day's total seconds of gun-related news coverage on an indicator for the occurrence of a mass shooting and 10 lags of that indicator. The results suggest that media attention to guns increases roughly 300% immediately following a mass shooting and that coverage remains elevated from pre-shooting levels for at least a week following the event. Table E2 presents similar results using the count of mass shooting fatalities as the independent variable instead of a mass shooting indicator variable.¹⁷

Table E1

Mass shootings and news coverage.

Dependent variable: Log (1 + seconds of news coverage)				
	(1)	(2)	(3)	(4)
Mass shooting	1.509*** (0.218)	1.510*** (0.220)	1.497*** (0.218)	1.443*** (0.214)
Lags of mass shooting (days):

L5		0.844*** (0.214)	0.869*** (0.214)	0.832*** (0.209)
L6		0.610*** (0.206)	0.620*** (0.206)	0.582*** (0.194)
L7		0.466** (0.208)	0.453** (0.207)	0.419** (0.202)
L8		0.255 (0.196)	0.237 (0.195)	0.194 (0.185)
L9		0.260 (0.197)	0.254 (0.197)	0.212 (0.187)
L10		0.302 (0.194)	0.300 (0.195)	0.258 (0.185)
Constant	1.544*** (0.025)	1.463*** (0.027)	1.136*** (0.060)	0.897*** (0.151)
Fixed effects				
Day-of-week	No	No	Yes	Yes
Month	No	No	No	Yes
Year	No	No	No	Yes
Observations (days)	9496	9487	9487	9487

Table E2

Mass shooting fatalities and news coverage.

Dependent variable: Log (1 + seconds of news coverage)				
	(1)	(2)	(3)	(4)
Mass shooting fatalities	0.282*** (0.028)	0.284*** (0.028)	0.280*** (0.027)	0.273*** (0.026)
Lags of fatalities (days):				
L1	0.307*** (0.030)	0.308*** (0.030)	0.306*** (0.030)	0.299*** (0.029)
L2		0.175*** (0.029)	0.175*** (0.029)	0.169*** (0.028)

¹⁸ Additionally, we estimated models with 10 leads of each indicator variable (not shown to conserve space) and none of the leads are statistically significant at conventional levels. This suggests that gun-related media coverage does not presage mass shootings (as would be the case if media reports about firearms caused shootings or reflected other contemporary events associated with mass shootings).

Table F2

Linear probability model for mass shooting using policy variables.

Dependent variable: indicator for state-year with a mass shooting.		
	(1)	(2)
Handgun waiting period (days)	0.002 (0.005)	0.002 (0.005)
Long-gun waiting period (days)	−0.005 (0.019)	−0.005 (0.020)
Age 18+ for transaction	0.031 (0.026)	0.026 (0.028)
Age 21+ for transaction	−0.067 (0.057)	−0.080 (0.056)
Handgun permit system	−0.137 (0.094)	−0.136 (0.100)
Background check, all handgun sales	−0.066 (0.080)	−0.066 (0.085)
Background check, all firearm sales	0.019 (0.116)	−0.005 (0.127)
Assault weapons ban	0.042 (0.051)	0.050 (0.053)
Shall issue concealed carry	−0.010 (0.038)	−0.006 (0.039)
No permit needed concealed carry	0.162 (0.188)	0.181 (0.184)
Log population	−0.494 (0.325)	−0.445 (0.310)
Political controls	No	Yes
Demographic controls	Yes	Yes
State FE	Yes	Yes
Year FE	Yes	Yes
Observations	1250	1250

Note: *Handgun Waiting Period* is the number of days purchasers must wait before accepting delivery of a handgun. *Long-gun Waiting Period* is similarly defined for long-guns (e.g. rifles and shotguns). *Age 18+ Transaction* is an indicator for laws that prevent vendors from selling handguns to minors or prevent minors from purchasing handguns. *Age 21+ Transaction* is defined the same way for persons under 21. *Handgun Permit System* is an indicator for states that require permits to purchase a handgun. *Background Check, All Handgun Sales* is an indicator for requiring a background check for all handgun transactions (including private sales). *Background Check, All Firearm Sales* is an indicator for requiring a background check for all firearm transactions (including private sales). *Assault Weapons Ban* is an indicator for states that ban some types of assault rifles or pistols. *Shall Issue Concealed Carry* is an indicator for states that require the permitting authority to grant a license to anyone meeting the minimum statutory qualifications (i.e. do not permit law enforcement discretion in issuing permits). *No Permit Needed Concealed Carry* is an indicator for states that allow concealed carry without a permit.

Appendix G. Placebo mass shooting analyses

Table G1

Placebo analysis for bill introductions (mirrors Table 2).

	Actual	Percentiles of placebo test statistic					
		1st	5th	10th	90th	95th	99th
Shooting indicator (model 4)	2.07	−3.98	−2.89	−2.47	0.55	0.87	1.59
Shooting fatalities (model 8)	3.29	−3.81	−2.87	−2.45	0.71	1.10	1.93

Table G2

Placebo analysis for enacted laws (mirrors Table 5).

	Actual	Percentiles of placebo test statistic					
		1st	5th	10th	90th	95th	99th
Tightening laws (models 2, 4)							
Pooled shooting	−0.49	−2.19	−1.43	−1.07	1.83	2.25	3.10
Dem. leg. × shooting	0.05	−2.43	−1.61	−1.35	1.48	1.96	2.84
Rep. leg. × shooting	0.01	−2.89	−1.71	−1.23	1.62	2.24	3.41
Split leg. × shooting	−0.95	−2.57	−1.49	−1.01	2.07	2.56	3.95
Loosening laws (models 6, 8)							
Pooled Shooting	1.51	−3.21	−2.26	−1.88	0.82	1.24	2.03
Dem. leg. × shooting	−0.63	−2.64	−1.85	−1.41	1.23	1.60	2.97
Rep. leg. × shooting	3.09	−3.02	−2.27	−1.98	0.71	1.09	1.73
Split leg. × shooting	0.40	−2.93	−2.02	−1.59	1.34	1.79	2.72

Notes: We randomly assign placebo mass shootings to state-years in which no actual shooting occurred with probability equal to each state's frequency of shootings, and randomly draw a fatality count from the empirical distribution of fatalities. We then re-run the models and calculate the test statistic for the placebo shooting and fatality coefficients. The above percentiles are based on 1000 replications. The "Pooled" rows in Table G2 mirror models 2 and 6 of Table 5 (the models without interaction effects). The legislature effects mirror models 4 and 8 for tightening and loosening laws respectively.

Appendix H. Dropping individual states

These analyses exclude each state, one at a time, from our sample. Each graph plots the resulting 50 regression coefficients (from smallest to largest) along with a 95% confidence interval and estimates using the full sample of all states. The state abbreviations in the figures indicate the state that was dropped from the sample and mark the resulting point estimate. The vertical bars represent 95% confidence intervals. The solid, horizontal line indicates the point estimate from the complete sample (presented in the text and tables). The dotted, horizontal lines represent the lower and upper bounds of the 95% confidence interval for the full sample coefficient estimate.

The results show that removing individual states has little effect on the coefficient estimates, supporting the claim that the effect of mass shootings on gun policy is not driven by an individual state or shooting.

Demographic controls	Yes	Yes	Yes	Yes	Yes	Yes
State fixed effects	Yes	Yes	Yes	Yes	Yes	Yes
Year fixed effects	Yes	Yes	Yes	Yes	Yes	Yes
Observations	1250	1250	1250	1250	1175	1175

Note: Robust standard errors clustered by state in parentheses. Stars following coefficients represent p -values less than 0.10 (*), 0.05 (**) and 0.01 (***). *Gun Suicide Pct.* is the 5-year moving average of the percentage of suicides that are firearm-related and is used to proxy for gun ownership (Cook and Ludwig, 2006). Models 1 and 4 show that the main results do not change when adding this control variable; the other models suggest that the response of Republican legislatures cannot be explained by rates of gun ownership. See note to Table 1 for other variable definitions.

Appendix J. Mass shootings as an instrument for gun policy

In this appendix we use mass shootings as an instrumental variable to study the impact of gun laws on gun deaths. We start with the following model:

$$\ln(D_{st}) = \alpha_s + \theta_t + \beta \text{Gun Control}_{st} + \delta' Z_{st} + \epsilon_{st}$$

where D_{st} is non-mass shooting gun deaths per 100,000 people in state s and year t , α_s and θ_t are state and year effects, Gun Control_{st} is an index representing the strictness of gun policy, and Z_{st} is a vector of controls –demographic, political, and economic factors—that potentially affect gun

deaths. We use the same variables as Levitt (1996) as controls, but also include dummies for Republican and Democratic trifectas or legislatures, and a dummy for Republican governors.

We do not directly observe $Gun\ Control_{st}$; instead, we observe the enactment of new laws that change gun policy. Therefore, we estimate the equation in first differences:

$$\Delta \ln(D_{st}) = \lambda_t + \beta New\ Gun\ Laws_{st} + \Delta Z_{st}\delta + \Delta \epsilon_{st}$$

where $New\ Gun\ Laws_{st} = \Delta Gun\ Control_{st}$ is negative for laws that loosen gun control and positive for laws that increase gun control (according to our coders, see data description). Based on our main results, we instrument for gun laws using the first lags of mass shooting fatalities and the interaction of lagged mass shooting fatalities with Republican control of state government. The former should be positively correlated with new laws and the latter negatively correlated with new laws.

We estimate the model using Fuller's (1977) modified LIML with $\alpha = 1$ (Baum et al., 2007). First stage results suggest the instruments are weak despite being jointly significant ($F = 5.98$) with the expected sign (Stock and Yogo, 2005). The coefficients on the exogenous instruments in the reduced form equation for firearm deaths are not significant, but also have the expected signs (negative for lagged mass shooting fatalities and positive for the interaction of lagged fatalities with Republican control of government). Our estimate $\hat{\beta}$ is -0.016 with standard error 0.013 . A conditional likelihood ratio test (Moreira, 2003; Andrews et al., 2006; Finlay and Magnusson, 2009) cannot reject the null hypothesis that $\beta = 0$ ($p = 0.24$). We also estimated models that include proxies for gun ownership. Including the percentage of suicides committed with a gun (Cook and Ludwig, 2006) does not change our inference.
